TECHNICAL NOTE 2331

WIND-TUNNEL INVESTIGATION OF A NUMBER OF TOTAL-PRESSURE

TUBES AT HIGH ANGLES OF ATTACK

SUBSONIC SPEEDS<sup>1</sup>

By William Gracey, William Letko, and Walter R. Russell

SUMMARY

The National Advisory Committee for Aeronautics is investigating the possibility of designing a fixed total-pressure tube which will remain insensitive to inclination of the air stream over a wide range of angle of attack throughout the subsonic and supersonic speed ranges. As the first step in this program the variation of total-pressure error with angle of attack of 39 total-pressure tubes has been determined for an angle-of-attack range of  $\pm 45^\circ$  and an indicated airspeed of 195 miles per hour. The design of these tubes was varied in such a manner that the effects of external shape, internal shape, and configuration of the total-pressure entry could be determined. The external shapes tested included cylindrical-, conical-, and ogival-nose sections. The internal shapes and total-pressure entries were varied on the basis of such factors as size of impact opening, shape of internal chamber, internal bevel, leading-edge sharpness, slant profile, and shielding (combined with venting).

The investigation showed that a shielded total-pressure tube (Kiel type) designed for end-mounting on a horizontal boom and having a vent area equal to 1.5 times the entrance area was the least sensitive to inclination of any of the tubes tested. The angle-of-attack range over which this tube remained insensitive to within 1 percent of the impact pressure was  $\pm 41.5^\circ$ .

A comparison of the calibrations of the remaining tubes showed that cylindrical tubes are less sensitive to misalignment than either conical or ogival-nose sections. For simple straight-bore cylindrical tubes, it was shown that the range of insensitivity may be increased by increasing the size of the impact opening. For tubes having a very large bore extending 1 tube diameter behind the nose, the misalignment characteristics may be improved still further by the use of a hemispherical rather

than a cylindrical chamber. Cylindrical tubes incorporating a  $15^{\circ}$  internal bevel extending about 1.5 tube diameters to the rear of the nose were shown to provide even greater insensitivity to misalignment. An important feature of this tube was a sharp leading edge which was found to be generally effective in increasing the range of insensitivity of total-pressure tubes.

For airspeed applications where it is not essential that a tube be insensitive to large negative angles of attack, the range of insensitivity at positive angles of attack may be extended by the use of a slant profile. The range of insensitivity of a large-bore tube, for example, was shifted from  $\pm 23^{\circ}$  to  $-13^{\circ}$  and  $32^{\circ}$  by means of a  $10^{\circ}$  slant profile. The sensitivity of this tube to angles of yaw and to angles of attack combined with angles of yaw up to  $15^{\circ}$  was shown to be no greater than that of a similar tube having a straight leading-edge profile.

#### INTRODUCTION

With the development of high-speed airplanes having low-aspect-ratio wings and the capability of flying to high altitudes, it has become possible for airplanes to reach extremely high angles of attack at high speeds. Under these conditions the total pressure measured by a conventional fixed total-pressure tube may be appreciably in error because of the inclination of the tube to the air stream. Although these errors may be avoided by mounting the tube on pivots and adding vanes so that the tube will always align itself with the air stream, this type of tube is considered undesirable for high-speed flight because of the possible serious consequences of structural failure when the tube is mounted ahead of the fuselage nose.

In order to establish the optimum design of a fixed total-pressure tube for use at high angles of attack, the National Advisory Committee for Aeronautics has inaugurated a wind-tunnel program for investigating the characteristics of a number of total-pressure tubes through a large range of angle of attack in both the subsonic and supersonic speed ranges. This paper presents the results of the subsonic tests of the first group of tubes to be investigated. In the interest of early publication of the test results, the data are being presented at this time without detailed analysis.

#### SYMBOLS

d diameter of impact opening of tube  
D body diameter of tube

H	total pressure of free stream
H'	total pressure measured by tube
$\Delta H$	total-pressure error ( $H' - H$ )
$q_c$	free-stream impact pressure
$\alpha$	angle of attack of total-pressure tube, degrees
$\psi$	angle of yaw of total-pressure tube, degrees

## APPARATUS AND TESTS

The 39 total-pressure tubes which were tested during this investigation are shown in figures 1 to 5. Design details and pertinent dimensions of each of the tubes are given in the calibration charts at the end of this paper. With the exception of tubes A-10 to A-13 and E-1, the body diameter of each of the tubes was 1 inch.

For purposes of comparison the 39 tubes have been divided into five groups on the basis of the external shape of the nose sections - cylindrical (series A),  $15^\circ$  conical (series B),  $30^\circ$  conical (series C),  $45^\circ$  conical (series D), and ogival (series E). The design of the various tubes in each of the five series was varied as regards both internal shape and configuration of total-pressure entry. It may be noted in figure 1 that tubes A-10 to A-13 were actually the same tube in which the number of exit orifices was increased on four successive tests. Similarly, tubes A-2 and A-3 were identical except for the thickness of the wall at the entry.

The tests were conducted in the 6- by 6-foot test section of the Langley stability tunnel. The tube support employed during these tests was a special U-shaped swivel mechanism (figs. 6 and 7) which was mounted on the side wall of the tunnel. This support was designed with the axis of rotation directly below the tip of the total-pressure tube in order that the total-pressure entry would remain at the same point in the air stream regardless of the angular setting of the tube. The inclination of the tube to the air flow was set by means of a control arm and an angular scale on the outside of the tunnel wall (figs. 7 and 8). Possible errors caused by deflection of the support mechanism were investigated at an angular setting of  $45^\circ$  and were found to be negligible.

Each tube was tested at an impact pressure of 100 pounds per square foot or an indicated airspeed of about 195 miles per hour. At this speed the tube was rotated through an angular range of  $\pm 45^\circ$  in  $5^\circ$  increments.

For each setting of the tube the total-pressure error was determined by measuring the pressure difference between the test tube and a fixed pitot-static tube mounted on the opposite side of the tunnel (fig. 6). The pitot-static tube was also used to provide a measure of the impact pressure at which the tests were conducted. The accuracy of the measurements of  $\Delta H/q_c$  was estimated to be within 0.002.

#### RESULTS AND DISCUSSION

The results of the tests of the 39 total-pressure tubes are presented in figures 9 to 47. The symbol  $\Delta H$  shown in these figures represents the total-pressure error, which is defined by the relation  $H' - H$ , where  $H'$  is the total pressure measured by the tube and  $H$  is free-stream total pressure. These total-pressure errors are presented as fractions of the impact pressure  $q_c$  and are plotted as a function of the angle of attack  $\alpha$  (or angle of yaw  $\psi$ ) of the tubes.

In the following discussion the calibrations of each series of tubes are treated separately in order to show the effects of internal shape and configuration of the total-pressure entry on the characteristics of a given external shape. At the end of this discussion the calibrations of comparable tubes in each of the five series are compared to show the effect of variations in external shape. The criterion which has been chosen for these comparisons is the range of angle of attack over which the tube reads correctly to within 1 percent of the impact pressure. For convenience in making these comparisons the range of insensitivity of the 39 tubes has been summarized in table I.

Cylindrical-nose tubes - series A. - The calibrations of 13 total-pressure tubes having a straight external wall are presented in figures 9 to 21. The design of these tubes was varied in such a manner that the effects of size of impact opening, shape of internal chamber, slant of leading-edge profile, internal bevel, and shielding (combined with venting) might be investigated.

The variation of tube sensitivity with impact-opening size (or more specifically, the ratio of impact-opening diameter  $d$  to tube diameter  $D$ ) may be determined by comparing figures 9 to 11. Examination of the two extreme cases, tubes A-1 and A-2, will show that the tube having the larger ratio of  $d/D$  has the greater insensitivity to misalignment. For example, the range of insensitivity of the large-bore tube A-2 ( $\frac{d}{D} = 0.98$ ) is  $\pm 23^\circ$ , whereas that of the small-bore tube A-1 ( $\frac{d}{D} = 0.125$ ) is only  $\pm 11^\circ$ . Small differences in impact-opening size, on the other hand, have a negligible effect on the range of insensitivity of the tube. Figures 10 and 11 show that for a decrease in  $d/D$  from 0.98 (tube A-2) to 0.96

varies in a similar manner. It may be noted, however, that the total-pressure errors of the blunt-nose tubes having cone angles of  $30^\circ$  and  $45^\circ$  are smaller than those of the sharp-nose tubes at the higher angles of attack.

The effect of impact-opening size on the characteristics of a conical-nose tube of  $30^\circ$  is shown in figures 28, 31, and 32. These figures show that, for an increase in the size of the impact opening from  $1/16$  to  $1/8$  to  $3/16$  inch, the range of insensitivity of the tube is increased from  $\pm 15.5^\circ$  to  $\pm 17.5^\circ$  to  $\pm 19^\circ$ , respectively. These results are similar to those obtained with cylindrical tubes in showing the advantage of large  $d/D$  ratios.

The characteristics of conical-nose sections having internally beveled total-pressure entries may be shown by comparing the calibrations of tubes B-4 to B-6, C-6 to C-8, and D-4 to D-6 (figs. 25 to 27, 33 to 35, and 39 to 41). These curves show that for each of the three cone angles the tubes having an internal bevel of  $15^\circ$  are less sensitive to misalignment than tubes having  $20^\circ$  and  $25^\circ$  bevels. It will be recalled that this variation of tube sensitivity with internal bevel angle is the same as that shown for internal bevels on cylindrical tubes.

Ogival-nose tubes - series E. - Calibrations of total-pressure tubes having an ogival-nose section similar to that of the F.S.S.C. No. 18-T-4554 pitot-static tube are presented in figures 42 to 47. The total-pressure entries of these tubes were varied on the basis of leading-edge sharpness, profile slant, and internal bevel.

Tube E-1 was an actual F.S.S.C. No. 18-T-4554 tube ( $\frac{29}{32}$ -inch body diameter) which was adapted for mounting on the swivel test rig used in this investigation. The total-pressure entry of this tube was reworked for these tests to a sharp leading edge by reaming the impact opening to a diameter of 0.29 inch. The nose shape of the remaining tubes was patterned after tube E-1 except that the body diameter for these tubes was 1 inch.

An approximate indication of the effectiveness of sharpening the leading edge of this type tube may be obtained by comparing the tests of tubes E-1 and E-2 (figs. 42 and 43). The sharp-edged entry remained insensitive over a range of angle of attack of  $\pm 16^\circ$ , whereas the blunt-nosed tube was insensitive from only  $-1.5^\circ$  to  $11.5^\circ$ . The asymmetry of the curve for the second tube is, of course, due to the  $10^\circ$  oblique profile. If the forward profile of this tube had been straight, the curve would presumably have been symmetrical about zero angle of attack and the tube insensitive over a range of  $\pm 6.5^\circ$ .

The effect of changing the slant of the leading-edge profile from  $10^\circ$  to  $20^\circ$  is shown in figures 43 and 44. These curves show that, whereas tube E-2 is insensitive over an angle-of-attack range from  $-1.5^\circ$  to  $11.5^\circ$ , tube E-3 is insensitive from  $8.5^\circ$  to  $21.5^\circ$ . In other words, the effect of increasing the slant angle from  $10^\circ$  to  $20^\circ$  is a shift of the curve on the angle-of-attack scale of  $10^\circ$ .

The effect of varying the internal bevel from  $15^\circ$  to  $25^\circ$  on an ogival-shaped tube is shown in figures 45 to 47. As shown by these figures, the range of insensitivity decreases from  $\pm 19^\circ$  to  $\pm 18.5^\circ$  to  $\pm 18^\circ$  as the bevel angle increases from  $15^\circ$  to  $20^\circ$  to  $25^\circ$ . The variation of tube sensitivity with bevel angle is, therefore, the same as that for cylindrical- and conical-nose tubes. The magnitude of the variation, however, for equal changes in bevel angles is somewhat less than that for the cylindrical and conical tubes.

An interesting phenomenon which was encountered during these tests is that at high angles of attack the indications of some of these tubes became very erratic and these irregularities were accompanied by a loud whistling sound which could be heard through the walls of the tunnel. When tube E-1, for example, was moved through the angle-of-attack range, the indicated pressures would sometimes follow the solid line shown in figure 42 and for this case no whistling could be discerned. During other tests, however, the indicated pressures would follow the dashed curve (that is, the total-pressure errors were increased) and under these conditions the tube whistled. The exact cause of this effect is not entirely clear, for it was noted during the tests of tubes E-1 and E-3 but not of tube E-2 (which had a chamber of the same size and shape as that of tube E-3 and differed only in the obliqueness of the profile). With tube E-1 the effect began at angles of attack of  $\pm 40^\circ$ . With tube E-3 the whistling began at  $-25^\circ$  which, when added to the effective zero ( $15^\circ$ ) of this tube, is also equivalent to  $40^\circ$ . These acoustic effects could probably be eliminated by decreasing the length of the internal chamber, but just what the critical length is for chambers of this shape was not determined during this investigation.

External shape - series A, B, C, D, and E. - The effect of external shape on the misalignment characteristics of total-pressure tubes can be determined by comparing tubes having the same type of total-pressure entry in each of the five series. For example, comparison of tubes having an internal bevel of  $20^\circ$  (figs. 16, 26, 34, 40, and 46) will show that the range of insensitivity of the tubes having a straight external wall is greater than that of the tubes having conical- and ogival-nose sections. The range of insensitivity of the  $15^\circ$  conical tube, in turn, is greater than that of the conical tubes of  $30^\circ$  and  $45^\circ$  and is about the same as that for the ogival tube. Similar trends may be noted from comparison of tubes which have other types of entry.

## CONCLUDING REMARKS

The more significant conclusions which may be drawn from the results of subsonic tests of the total-pressure errors of 39 total-pressure tubes over an angle-of-attack range of  $\pm 45^\circ$  are summarized in the following paragraphs.

A shielded total-pressure tube (Kiel type) designed for end-mounting on a horizontal boom and having a vent area equal to 1.5 times the entrance area exhibited the least sensitivity to inclination of any of the tubes tested. The angle-of-attack range over which this tube remained insensitive to within 1 percent of the impact pressure was  $\pm 41.5^\circ$ .

From the standpoint of the various design factors which were studied during the investigation, the following results appear noteworthy. Tubes having a cylindrical external shape were less sensitive to misalignment than tubes having conical- or ogival-nose sections. For simple, straight-bore cylindrical tubes, the range of insensitivity was increased by increasing the relative size of the impact opening. For tubes having a very large bore extending 1 tube diameter behind the nose, the misalignment characteristics were improved still further by the use of a hemispherical rather than a cylindrical chamber. Cylindrical tubes incorporating a  $15^\circ$  internal bevel extending about 1.5 tube diameters to the rear of the nose provided even greater insensitivity to misalignment. An important feature of this tube was a sharp leading edge which was found to be generally effective in increasing the range of insensitivity of total-pressure tubes.

For airspeed applications where it is not essential that a tube be insensitive to large negative angles of attack, the range of insensitivity at positive angles of attack was extended by the use of a slant profile. The range of insensitivity of a large-bore tube, for example, was increased from  $\pm 23^\circ$  to  $-13^\circ$  and  $32^\circ$  by means of a slant profile of  $10^\circ$ . The sensitivity of this tube to angles of yaw and to angles of attack combined with angles of yaw up to  $15^\circ$  was no greater than that of a similar tube having a straight-leading-edge profile.

Abstract

Calibrations of 39 total-pressure tubes for an angle-of-attack range of  $\pm 45^\circ$  and an indicated airspeed of 195 miles per hour are presented. The configurations of the various tubes differed as regards external shape, internal shape, and type of total-pressure entry. External shapes tested included cylindrical-, conical-, and ogival-nose sections. Internal shapes and total-pressure entries were varied on the basis of such factors as size of impact opening, leading-edge sharpness, chamber shape, internal bevel, slant profile, and shielding (combined with venting). The effect of these design variables on the sensitivity of the tubes to angle of attack is discussed.

Abstract

Calibrations of 39 total-pressure tubes for an angle-of-attack range of  $\pm 45^\circ$  and an indicated airspeed of 195 miles per hour are presented. The configurations of the various tubes differed as regards external shape, internal shape, and type of total-pressure entry. External shapes tested included cylindrical-, conical-, and ogival-nose sections. Internal shapes and total-pressure entries were varied on the basis of such factors as size of impact opening, leading-edge sharpness, chamber shape, internal bevel, slant profile, and shielding (combined with venting). The effect of these design variables on the sensitivity of the tubes to angle of attack is discussed.

Abstract

Calibrations of 39 total-pressure tubes for an angle-of-attack range of  $\pm 45^\circ$  and an indicated airspeed of 195 miles per hour are presented. The configurations of the various tubes differed as regards external shape, internal shape, and type of total-pressure entry. External shapes tested included cylindrical-, conical-, and ogival-nose sections. Internal shapes and total-pressure entries were varied on the basis of such factors as size of impact opening, leading-edge sharpness, chamber shape, internal bevel, slant profile, and shielding (combined with venting). The effect of these design variables on the sensitivity of the tubes to angle of attack is discussed.
